Combinational Circuit Design

Karnaugh Map Technique

Maurice Karnaugh

- Goal is to minimize a given logic function
 - Algebraic techniques lack rules to predict each successive step
 - Karnaugh Map or K-map technique is a simple and straightforward procedure for minimizing Boolean function
-
- K-map is a pictorial representation of the truth-table of a given function
 - Humans can easily find patterns in the K-map that provide opportunities of minimization

K-Map: Representation

- K-map is a diagram made up of squares
 - Each square represents one minterm of the function
- Any Boolean function can be represented as a sum of minterms
 - A function is represented in the K-map by those squares whose minterms are included in the function

K-Map: Simplification

- Simplified expression obtained using K-map will always be in SOP or POS form
- Simplest expression is one with ***minimum number of terms*** and with ***smallest number of literals in each term***
 - This expression produces a circuit diagram with a minimum number of gates and the minimum number of inputs to each gate
- Simplest expression may not be unique for a given function

K-Map: Two variables

m_0	m_1
m_2	m_3

$x \backslash y$		y	
		0	1
x	0	m_0 $x'y'$	m_1 $x'y$
	1	m_2 xy'	m_3 xy

- Two variables:

➤ Four minterms: four squares

- $m_0 = x'y'$
- $m_1 = x'y$
- $m_2 = xy'$
- $m_3 = xy$

- 0/1 marked in each row/column represents the value of the variable
- Variable x appears complemented in row 0 and non-complemented in row 1
- Variable y appears complemented in column 0 and non-complemented in column 1

K-Map: Two variables functions

Function is represented on a K-map by marking the square as '1' if the corresponding minterms belong to that function

Problem: Represent the function $f(x, y) = xy$ on a K-map

Problem: Represent the function $f(x, y) = x + y$ on a K-map

K-Map: Three variables

m_0	m_1	m_3	m_2
m_4	m_5	m_7	m_6

		y			
		yz			
		00	01	11	10
x	0	m_0 $x'y'z'$	m_1 $x'y'z$	m_3 $x'yz$	m_2 $x'yz'$
x	1	m_4 $xy'z'$	m_5 $xy'z$	m_7 xyz	m_6 xyz'
		z			

- Three variables:

- Eight minterms: eight squares

- Minterms are: $m_0 = x'y'z'$, $m_1 = x'y'z$, $m_2 = x'yz'$, $m_3 = x'yz$, $m_4 = xy'z'$, $m_5 = xy'z$, $m_6 = xyz'$ and $m_7 = xyz$

- Minterms are not arranged in a binary sequence but similar to Gray code

- Only one bit changes in value from one adjacent column to the next

- Any two adjacent squares in the K-map differ by only one variable

- By adjacent it is meant **horizontally** or **vertically**, but NOT diagonally

- This property is exploited in **simplification**

K-Map: Basis of simplification

		y			
		yz	00	01	11
x	0	m_0 $x'y'z'$	m_1 $x'y'z$	m_3 $x'yz$	m_2 $x'yz'$
	1	m_4 $xy'z'$	m_5 $xy'z$	m_7 xyz	m_6 xyz'

- Consider any two adjacent squares

- m_5 and m_7 ($xy'z$ and xyz): variable y is complemented and also not-complemented
- m_1 and m_5 : $x'y'z$ and $xy'z$: variable x is complemented and also not-complemented

- Sum of two minterms in adjacent squares can be simplified to a single product term consisting of only two literals.

- $m_5 + m_7 = xy'z + xyz = xz(y + y') = xz$: variable y is removed
- $m_1 + m_5 = x'y'z + xy'z = y'z(x + x') = y'z$: variable x is removed

- Any two minterms in adjacent squares that are OR'ed together will cause a removal of the dissimilar variable.

K-Map: Three variables simplification

Simplify $f(x, y, z) = \Sigma m(2, 3, 4, 5)$

- First represent the given function on K-map
- Find possible adjacent squares:
 - m_3 and m_2 : $= x'yz + x'yz' = x'y$
 - m_4 and m_5 : $= xy'z' + xy'z = xy'$

$$f(x, y, z) = x'y + xy'$$

K-Map: adjacent squares

		y			
		00	01	11	10
x	0	m_0 $x'y'z'$	m_1 $x'y'z$	m_3 $x'yz$	m_2 $x'yz'$
	1	m_4 $xy'z'$	m_5 $xy'z$	m_7 xyz	m_6 xyz'

- Consider the squares at the boundaries
 - m_0 and m_2 : $x'y'z'$ and $x'yz'$ [Differ in only y' and y]
 - m_4 and m_6 : $xy'z'$ and xyz' [Differ in only y' and y]
- Minterms differ by one variable only

- The corresponding squares at the boundaries behave as “adjacent squares”
- Considering the K-map as being drawn on a surface in which the right and left edges touch each other to form adjacent squares

K-Map: Three variables simplification (two squares)

Simplify $F(x, y, z) = \Sigma m(3, 4, 6, 7)$

- First represent the given function on K-map
- Find possible adjacent squares:
 - m_3 and m_7 : $= x'yz + xyz = yz$
 - m_4 and m_6 : $= xy'z' + xyz' = xz'$

$$f(x, y, z) = yz + xz'$$

For three variables function:

When two adjacent squares are combined, product terms with two literals remain

K-Map: Three variables simplification (four squares)

Simplify $F(x, y, z) = \Sigma m(0, 2, 4, 6)$

- First represent the given function on K-map

		y			
		00		01	$\overbrace{11 \quad 10}$
x	yz				
	0	m_0 $x'y'z'$	m_1 $x'y'z$	m_3 $x'yz$	m_2 $x'yz'$
x	1	m_4 $xy'z'$	m_5 $xy'z$	m_7 xyz	m_6 xyz'
		$\underbrace{\hspace{10em}}_z$			

- Find possible adjacent squares:

$$\triangleright m_0, m_2, m_4 \text{ and } m_6: = x'y'z' + x'yz' + xy'z' + xyz' = x'z' + xz' = z'$$

$$f(x, y, z) = z'$$

For three variables function:

When four adjacent squares are combined, product terms with only one literals remain

K-Map: Bigger combination, fewer literals

- The number of adjacent squares that may be combined must always represent a number that is a power of two, such as 1, 2, 4, and 8 [otherwise number of literals will not reduce]
- As more adjacent squares are combined, we obtain a product term with fewer literals

For three variables function:

- One square represents one minterm, giving a term with three literals
- Two adjacent squares represent a term with two literals
- Four adjacent squares represent a term with one literal
- Eight adjacent squares encompass the entire map and produce a function that is always equal to 1
